Re-engineering the Student Renewal → Class Scheduling Pipeline

AI Program Manager (Operations) — Take-Home Case Report

Deliverables A (audit), B (workflow), D (dashboard, SOP, 30-60-90) + summary of C (prototype) · Prepared by Hardik Choudhary · Data snapshot 2026-11-03 18:00 IST · Repo: **bambinos-ops-renewal-automation**

1 of 11	₹1,21,600	6	42%
paid renewals that reached scheduled classes	paid but not scheduled (10 invoices)	invoices stuck more than 12 h (₹68,100)	of outstanding renewals are zero-touch with the new design

Executive summary

The problem. After a parent pays for a renewal, the child must pass through four tables and three manual handoffs (teacher form, Ops approval, batch selection) before classes are scheduled. In the 13-invoice sample, only **1 of 11** fully paid renewals reached class_schedule_bookings. Ten paid invoices worth **₹1,21,600** are waiting, six of them for more than 12 hours; the oldest (invoice 84902, paid on a Sunday) has waited about 52 hours and was already approved by Ops.

The insight. This is not a lazy-teacher problem. When teachers file the form they do it fast (median 25 minutes after payment). The pipeline leaks because steps 2 and 3 re-type and re-check data the invoice already contains, so typos, duplicates and missing forms are common, and because every failure state is a dead end with no owner, alert or retry. Ops approval is not the finish line: **3 of the 4 approved forms still have no classes**.

The redesign. (1) Remove the teacher form for same-batch renewals. (2) A rules engine reconciles every payment within minutes and schedules clean renewals with no human step. (3) Every exception gets one reason code, one named owner, a drafted WhatsApp/Slack message and an SLA timer. (4) The Head of Operations opens one dashboard each morning that shows stuck money first.

The proof. I built the engine three ways (Google Sheet formulas, a Python script, and the JavaScript rules for n8n); all three give identical results on all 13 invoices. Of the 12 outstanding renewals: **5 are zero-touch (42%)** (auto-approve or a safe automatic fix), **3 need only a one-tap parent confirmation** (together 8 of 12, 67%), and only **4 need real human judgement** (a discount, a batch change, and two payment problems).

The rollout. Shadow mode for 30 days (the engine suggests, Ops still approves), a pilot with a small teacher group, then all 200+ teachers in cohorts by day 90. A kill switch returns everything to the manual process at any time, so live class schedules are never put at risk.

Honesty note: the sample is 13 invoices, so the percentages show what the design does on the provided data, not production rates. Section 6 lists every assumption and how I would validate it on real data.

1. Current state: how a renewal travels today

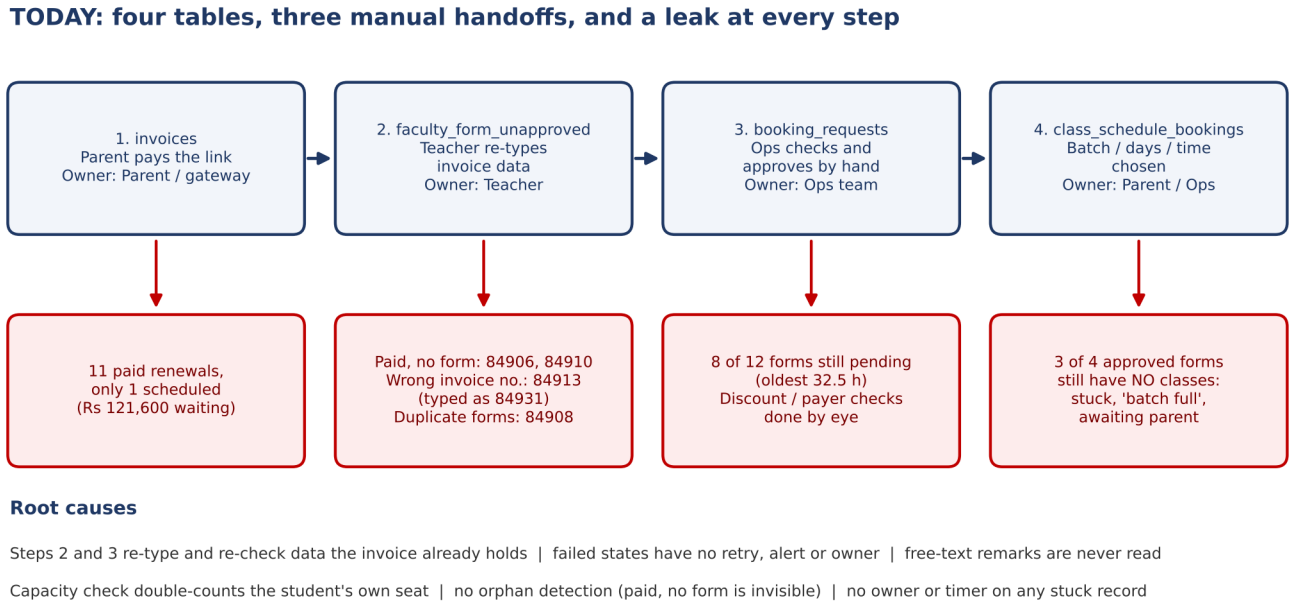

Figure 1. The four-table chain with the leak found at each step (numbers from the provided CSVs).

Method. I traced every invoice through all four tables and the reference sheet (active batches and students), joining on invoice_id, user_id, student_id, classbatch_id and faculty_form_id. Names and phones are masked in the data, so I matched on IDs first and used masked strings only as a secondary check. Soft-deleted rows were ignored. I then wrote down every place a paid student could stall.

Handoffs and owners today

Handoff	Who acts	What goes wrong in the data
Payment → form	Teacher	Form never filed (84906, 84910); wrong invoice number typed (84913 entered as 84931); form filed twice (84908); wrong amount (84909 shows ₹10,500 for a ₹5,250 instalment)
Form → booking request	Ops exec (manual)	8 of 12 forms pending, oldest 32.5 h; discount and payer differences caught only by eye (84904, 84907)
Booking request → schedule	Parent or Ops	Dead ends: stuck at allocation (84902), false "batch full" (84905), waiting on parent with no reminder (84912)

2. Deliverable A: root-cause audit and leakage

2.1 Invoice-by-invoice audit (every row is evidence from the CSVs)

Invoice	What the data shows	Reason code	Outcome
84901	Fully done in 1 h 45 min. But only 2 of 24 purchased sessions exist in table 4 (rolling window or under-scheduling: to confirm with Ops)	SESSIONS_UNDER_SCHEDULED (info)	DONE
84902	Form approved, booking 5502 stuck at Pending_Batch_Allocation for ~48 h; batch 9202 has 5 of 6 seats. Paid on a Sunday	STUCK_AT_ALLOCATION	AUTO-FIX
84903	Clean same-batch renewal; amount, IDs and batch capacity all fine; form still pending after 32 h	none	AUTO
84904	Invoice mobile, email and payer name differ from the registered parent; teacher remark: "Mother paid from her number". user_id and student_id match	PAYER_MISMATCH	SOFT
84905	Booking failed as batch full (6/6), but the student already holds a seat in that batch; a same-batch renewal needs no new seat	FALSE_BATCH_FULL	AUTO-FIX
84906	Paid via Stripe (Dubai parent), ₹18,000, no teacher form at all	ORPHAN_NO_FORM	SOFT
84907	20% discount (₹9,500 → ₹7,600) offered by the teacher as a "retention scholarship"; no approval trail	DISCOUNT_NEEDS_APPROVAL	HUMAN
84908	Two forms (3308, 3309) for one invoice because the browser froze; would create a double booking	DUPLICATE_FORM	AUTO-FIX

Invoice	What the data shows	Reason code	Outcome
84909	Instalment 1 of 2: ₹5,250 paid of ₹10,500. Teacher's form claims ₹10,500 paid and 24 sessions	PARTIAL_PAYMENT + AMOUNT_MISMATCH	BLOCK
84910	Paid ₹11,000, no teacher form	ORPHAN_NO_FORM	SOFT
84911	Gateway status Failed, no payment id; teacher forwarded a UPI "processing" screenshot	PAYMENT_NOT_CONFIRMED	BLOCK
84912	Parent wants a weekend 11 AM batch. Form approved, booking waits on the parent, nobody nudges. No Gita batch exists at that slot (batch 9205 is Sat/Sun 11:00 but it is Chess)	BATCH_CHANGE_PENDING + NO_MATCHING_BATCH	HUMAN
84913	Form cites invoice 84931 (digits swapped). The invoice's parent name also contains Cyrillic look-alike letters, which silently breaks exact name matching	INVOICE_ID_TYPO + HOMOGLYPH_MISMATCH	AUTO-FIX

Outcome key: AUTO = clean, zero touch; AUTO-FIX = safe defect repaired automatically; SOFT = one-tap parent confirmation; HUMAN = needs judgement; BLOCK = payment problem, never schedule.

2.2 Systemic failure modes (beyond the 13 rows)

Human behaviour	Data mismatches	Process design	Visibility
Teachers forget, delay or double-submit; no reminder or SLA Discounts offered informally, no approval trail Ops approves in batches, so evenings and weekends wait Free-text remarks carry key facts nobody reads	Payer differs from registered parent Invoice ID typos (transposed digits) Look-alike Unicode characters break exact match Form amount or sessions differ from what was paid Matching a batch on days/time alone can pick the wrong class	Steps 2 and 3 re-type and re-verify known data Capacity check counts the student's own seat Failed states have no retry, alert or owner Paid-but-no-form is invisible No idempotency: one invoice can create two bookings	No single "paid but not scheduled" number No timer from payment to first class No named owner on any stuck record Weekend delays are not measured

2.3 Quantifying the leakage

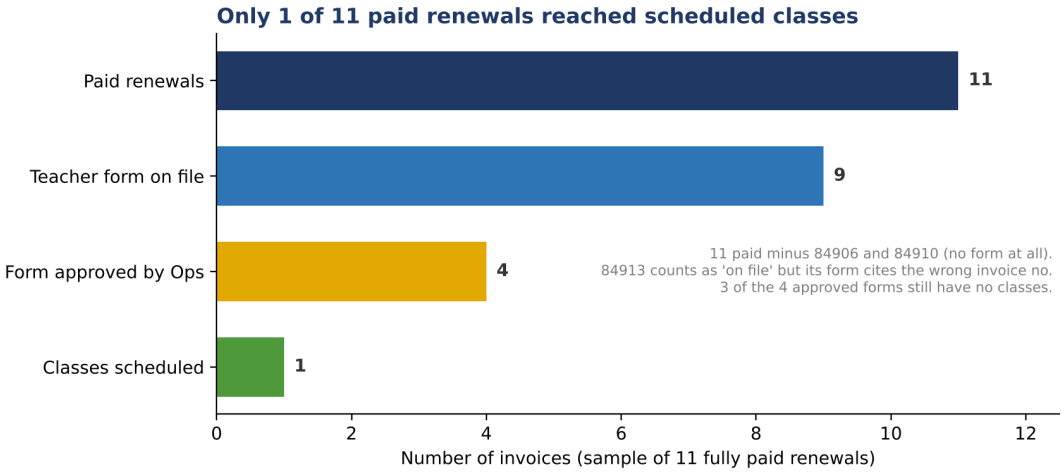

Figure 2. Funnel of the 11 fully paid renewals in the sample (snapshot 2026-11-03 18:00).

Baseline number (sample)	Value	Why it matters
Paid renewals that reached scheduled classes	1 of 11 (9%)	The headline leak
Paid but not scheduled	10 invoices, ₹1,21,600	Revenue at risk and broken parent experience
Stuck more than 12 h	6 invoices, ₹68,100	The Ops Head's first morning question
Oldest stuck invoice	84902, about 52 h	Paid Sunday, approved by Ops, still no classes
Forms pending Ops approval	8 of 12; oldest 32.5 h	The manual queue
Approved forms that actually got classes	1 of 4	Approval is not the finish line
Paid with no valid form	3 (84906, 84910, and 84913 via a typo)	Orphans: invisible today

Baseline number (sample)	Value	Why it matters
Teacher delay when a form is filed	median 25 min, max 50 min	Teachers are fast; the process is the problem
Best-case payment to schedule today	1 h 45 min (invoice 84901)	Sets the SLA target (2 h, automatic)

2.4 Metrics and SLAs that are broken or invisible today

Metric	Definition (source tables)	Owner
Orphaned Invoice Rate	Paid renewal invoices with no valid form after N h ÷ all paid renewals (invoices, forms)	Ops Head
Payment-to-Schedule Turnaround	First class_schedule_bookings.created_at − invoices.paid_at; median and p90	Ops Head
Payment-to-Form time / Form-to-Approval time	Teacher step and Ops step measured separately (forms, invoices)	Ops lead
Approval-to-Schedule time	Scheduling timestamp − approved_at; exposes the dead-end states (booking_requests)	Ops lead
Stuck Invoice Count (>12 h) and Revenue at Risk	Paid, no schedule row, older than threshold; sum of net_amount	Ops Head
Auto-Approval Rate	Renewals scheduled with zero human touch ÷ all renewals	Program Mgr
Duplicate Form Rate / Mismatch Rate	Invoices with more than one form; forms with ID, amount or phone mismatch	Ops lead
Exception Resolution Time	Flag raised → resolved, by reason code	Ops lead
Hours Saved	Auto-handled renewals × manual minutes per renewal	Program Mgr

Stage	Proposed SLA
Payment → booking request created (happy path)	≤ 15 minutes, automatic
Payment → classes scheduled (clean same-batch)	≤ 2 hours, automatic (best case today is 1 h 45 min, and manual)
Orphan (paid, no form)	Alert at 2 h after payment; escalate to Ops at 12 h
Exception acknowledged / resolved	≤ 4 working hours / ≤ 24 hours
Parent batch-selection reminders	At 24 h and 48 h, then escalate to Ops
Weekends and holidays	Automation runs 24x7; one on-call Ops owner

3. Deliverable B: the re-engineered "zero-touch" workflow

3.1 First principles: should each step exist?

Today's step	Why it exists	Verdict
Teacher fills the renewal form	Ops needs to know who paid and what they chose	**Eliminate for same-batch renewals.** The invoice and the student record already hold it. Capture intent when the payment link is created, or confirm with the parent in one tap
Ops compares invoice vs form	Catch typos, wrong amounts, unpaid links	**Automate.** A rules engine is faster and does not make typos
Ops approves into booking_requests	Control gate	**Keep only for exceptions.** Clean renewals pass automatically
Parent or Ops selects the batch	Parent may want a change	**Skip for same-batch.** Keep only for real batch changes, with reminders

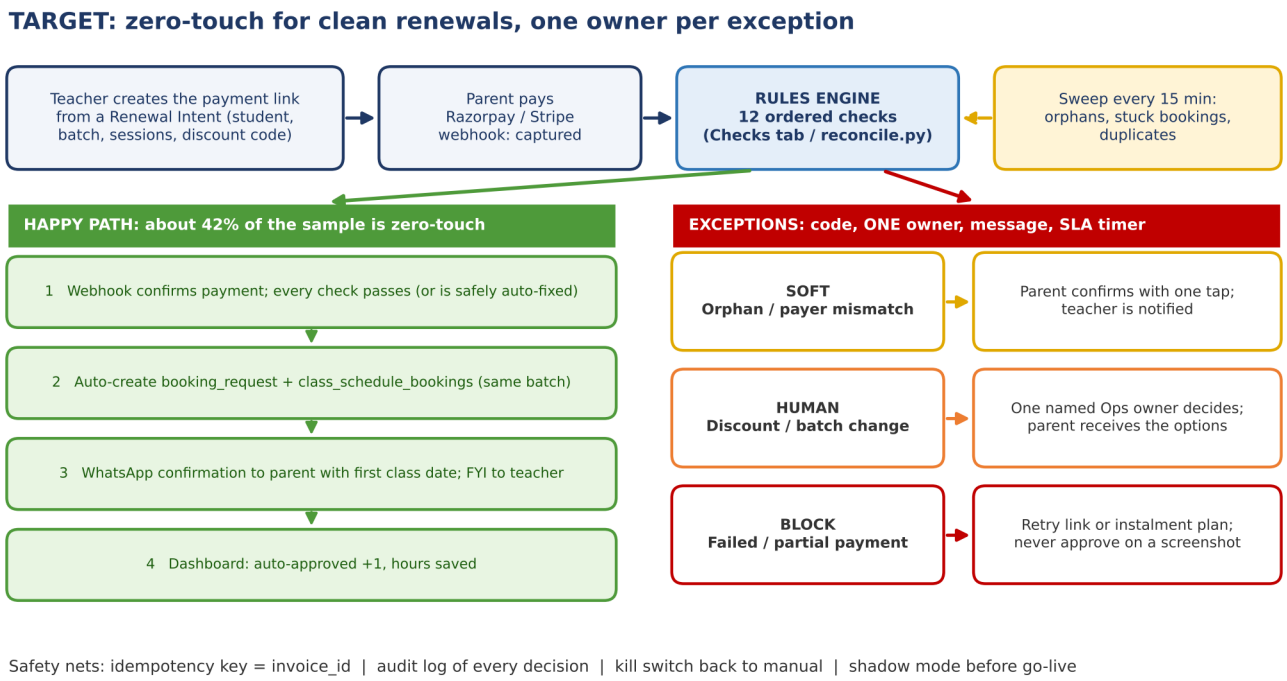

Figure 3. Target-state workflow: one rules engine, two lanes, one owner per exception.

3.2 What can be fully eliminated (the happy path)

A renewal is zero-touch when **all** are true: payment is Paid on the gateway; the amount equals the expected fee (or a pre-approved discount); IDs agree across invoice, form and reference; the student continues in the same batch and the batch is active; no duplicate form exists; and the payer matches the registered parent (or soft-matches). The engine then creates the booking request and the schedule rows, sends the parent a WhatsApp confirmation with the first class date, and tells the teacher "nothing to do". A 15-minute sweep also catches anything the webhook missed (orphans, stuck bookings, duplicates), so no paid invoice can stay invisible.

3.3 Smart exception handling: code → one owner → message → timer

Reason code	Owner	What the automation does	Message goes to
ORPHAN_NO_FORM	Parent (confirm) + Teacher (notify)	Auto-draft the booking from invoice + reference; ask the parent "same batch? reply 1 / change? reply 2"; escalate to Ops at 12 h	Parent, teacher
INVOICE_ID_TYPO	Automation	Unique match on user_id + student_id + amount repairs the link; logged	Teacher (FYI)
DUPLICATE_FORM	Automation	Keep the earliest form, mark the rest duplicate (idempotency on invoice_id)	Teacher (FYI)
HOMOGLYPH_MISMATCH	Automation	Normalise look-alike characters before matching; flag record for data clean-up	Ops log
STUCK_AT_ALLOCATION / FALSE_BATCH_FULL	Automation	Allocate the batch; re-run the capacity check without the student's own seat	Parent
PAYER_MISMATCH	Parent (registered number) + Ops	WhatsApp to the registered parent: reply YES if the payment was yours or family's, then approve	Parent, Ops
DISCOUNT_NEEDS_APPROVAL	Ops lead / Head	Approval request with the discount, reason and teacher; record who authorised	Head of Ops
AMOUNT_MISMATCH	Ops exec	Show form vs invoice side by side; schedule only what was paid	Ops, teacher
PARTIAL_PAYMENT	Ops exec / Finance	Hold full-term scheduling; decide what the instalment covers; remind parent for instalment 2	Parent, Ops
PAYMENT_NOT_CONFIRMED	Parent, then Ops	Send retry link; wait for the gateway webhook; never approve on a screenshot	Parent, teacher, Ops
BATCH_CHANGE_PENDING / NO_MATCHING_BATCH	Parent + Ops / Academics	Send options; reminders at 24 h and 48 h; Ops decides waitlist, new batch or existing slot. Match on class + educator + days + time, never days/time alone	Parent, Ops

3.4 Design decisions I would defend

Decision	Reasoning	Risk and mitigation
Replace the teacher form with parent confirmation for orphans	The parent knows what they want; the teacher is only re-typing	Parent may not reply → reminders, then an Ops phone call
Auto-approve only on strict rules	A wrong schedule for a paid child is costly	Shadow mode first, kill switch, audit log of every decision
Never approve on a screenshot	Only the gateway is the source of truth for payment	Retry link; wait for webhook; Ops checks the gateway
Idempotency key = invoice_id	Prevents duplicate bookings from double submissions	Unique constraint at table level
Discounts become policy, not ad hoc	Revenue leakage and inconsistency	Pre-approved discount codes with limits; anything else goes to approval
LLM reads and drafts, rules decide	LLMs are good at free text, bad at strict yes/no	The LLM never approves anything; deterministic rules do

3.5 Tools

n8n or Make for orchestration (payment webhook trigger + 15-minute sweep) · Razorpay/Stripe webhooks · Google Sheets or the production database · Metabase for the dashboard · WhatsApp Business API for parents and teachers · Slack for Ops · an LLM for reading teacher remarks and drafting messages (prompts in the repo). An importable n8n template is in the repo; it is a template and has not been run against live credentials.

4. Deliverable C: working prototype (summary; full detail in the repo)

The prototype reads the 5 CSVs and gives every invoice exactly one outcome. I built the same rules three ways so Ops can choose how to run them, and so each build checks the others:

Build	File	Who it suits
Google Sheets / Excel formulas (no code)	workflows_or_scripts/Renewal_Reconciliation_Sheet.xlsx (752 formulas, 0 errors)	Ops and PMs: open in Google Sheets, paste new rows, read every rule
Python script (reference engine)	workflows_or_scripts/reconcile.py (pandas only)	Reproducible results, outputs the 3 required files
n8n rules node + workflow template	n8n_rules_engine.js, n8n_renewal_workflow.json	Live automation: webhook and 15-minute sweep
LLM prompts	prompts/remark_parser.md, exception_triage.md, message_drafter.md	Reading teacher remarks, drafting messages
SQL for the dashboard	workflows_or_scripts/dashboard_queries.sql (9 MySQL queries)	Metabase questions on the production tables

Verification. The Sheet, the Python engine and the n8n JavaScript agree on the outcome and reason codes of all 13 invoices. A mutation test (changing one form amount in the Sheet) flipped invoice 84903 from AUTO_APPROVE to HUMAN / AMOUNT_MISMATCH, so the formulas are live. The SQL queries were run on the same data (via SQLite with date functions translated) and reproduce the same counts (for example 6 stuck invoices, 10 paid-unscheduled, ₹1,21,600).

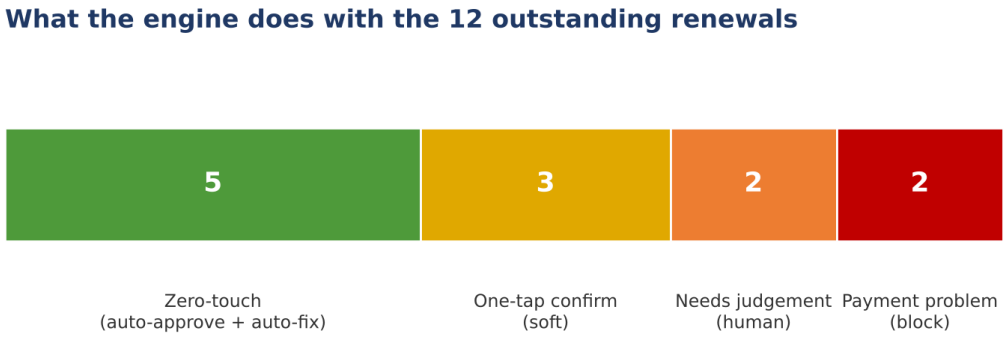

Figure 4. Engine outcome for the 12 outstanding renewals.

The three required outputs

Required output	File	What is in it
Auto-approved entries ready for class_schedule_bookings	results/auto_approved.csv, proposed_class_schedule_bookings.csv	5 renewals (84902, 84903, 84905, 84908, 84913) with any fix applied, plus 120 proposed session rows (24 each) in the shape of table 4
Flagged exceptions with exact reason codes	results/exceptions.csv	7 renewals (84904, 84906, 84907, 84909, 84910, 84911, 84912) with severity, owner, evidence values and the next action
Auto-drafted WhatsApp / Slack messages	results/messages.md and messages.json	21 messages for parents (with Hinglish), teachers, Ops execs and the Head of Ops, one ask and one deadline each

Example (invoice 84904, to the parent on the registered number): "*We received a payment of ₹12,000 for the student's renewal from a different mobile/email than the one on your account. Please reply YES if this was you or a family member, and we will schedule Tue,Thu 17:00 classes right away. Reply by Wed 04 Nov, 12 PM.*" The matching Ops message names the reason code, the evidence and the fallback (call the registered number).
Limits. Names and phones are masked in the source, so messages use masked names. Messages in the results are template-based for reproducibility; the LLM prompt writes them in production. Time zones for GCC/US tracks are not modelled. The n8n workflow and WhatsApp/Slack/LLM nodes are an importable template that was not executed against live services.

5. Deliverable D: dashboard, SOPs, rollout and 30-60-90 plan

5.1 The Ops Head's morning dashboard

Figure 5. Mock-up with the sample numbers (live version: Google Sheet 'Dashboard' tab, or Metabase on dashboard_queries.sql).

Block	Shows	Source
Health strip	Paid renewals, auto-handled %, scheduled %, revenue at risk, hours saved	Q9 + Checks
Stuck invoices > 12 h	Invoice, amount, owner, reason, hours stuck, next action (click-through)	Q2
Unapproved forms	Count by age bucket (0-2 h, 2-12 h, 12-24 h, >24 h)	Q3
Unscheduled bookings	By status: pending allocation, failed batch full, awaiting parent	Q6
Orphans and duplicates	Paid with no form (by teacher); duplicate and mismatched forms	Q1, Q4, Q5, Q8
Turnaround vs SLA	Payment-to-schedule median and p90; teacher and Ops step times	Q7

Red/amber/green against SLA; every row has a named owner; filters for date, teacher, category and region (India, GCC, US/UK). The teacher view is for coaching, not blame.

5.2 SOPs

Ops team (daily)	Teachers (what changes)
1. 9:00 open the dashboard; clear red items first (oldest, highest ₹) 2. Work each item by reason code using the template message; the system has already drafted it 3. Approval limits: execs approve ID/amount fixes and payer confirmations; discounts go to the Ops lead or Head 4. Never schedule on a screenshot; check the gateway status first 5. To override the automation, use the override column and write the reason (audit log) 6. Weekend rota: one on-call owner; automation keeps running 7. Escalate if an item breaches SLA: exec → lead (4 h) → Head (24 h)	1. For same-batch renewals there is **no renewal form**: create the payment link from the Renewal Intent (student, batch, sessions, discount code) 2. For a batch change or a discount, tick it on the Intent; do not type it in remarks 3. You will get a short message when the renewal is confirmed, or if the parent needs a nudge 4. If a parent says they paid but the link failed, ask for the bank reference; a screenshot is not enough 5. Questions: the #ops-renewals channel; response within 4 working hours

5.3 Rollout without breaking live class schedules

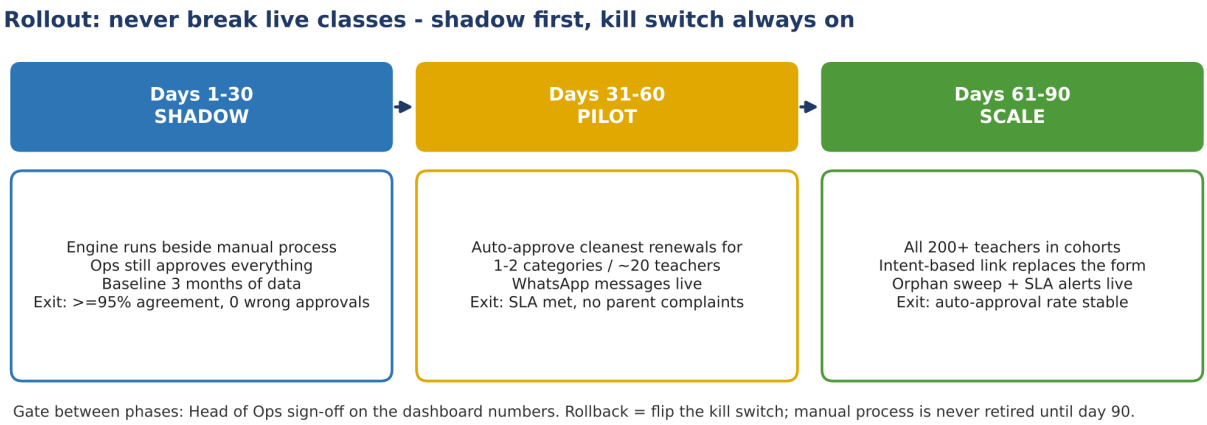

Figure 6. Phased rollout with exit gates and a kill switch.

Phase	What happens	Exit gate (Head of Ops signs off)
Days 1–30 Shadow	Pull 3 months of data and baseline every metric. Engine runs beside the manual process; compare its decision with Ops on every renewal. Train Ops; set up queues and owners	≥ 95% agreement on clean cases; 0 wrong auto-approvals; dashboard v1 trusted
Days 31–60 Pilot	Auto-approve the cleanest renewals for 1–2 categories and about 20 teachers. WhatsApp messages and remark parsing go live; discount-approval flow starts	Payment-to-schedule SLA met; no parent complaints; exception queue within SLA
Days 61–90 Scale	All 200+ teachers in cohorts. Intent-based payment link replaces the renewal form. Orphan sweep and SLA alerts live. Publish results	Auto-approval rate stable; hours saved and turnaround reported; plan phase 2 (instalment tracking, batch recommendation)

Change management for 200+ teachers and a 10-person Ops team

- **Teachers:** a 3-minute video, a one-page guide and weekly office hours; cohorts of about 40 teachers so support never gets overwhelmed; a champion teacher per cohort.
- **Ops team:** day-1 workshop on reason codes; every exec shadows the engine for two weeks; the Ops lead owns the rule book and approves any rule change.
- **Parents:** every message says what happened, what to do, and by when. Hinglish variant for parents; native-speaker review before launch.
- **Safety:** kill switch tested before go-live; manual process kept until day 90; freeze changes around term starts and peak renewal weeks.
- **Feedback loop:** weekly review of the exception log; every wrong call becomes a new rule or a prompt fix.

5.4 30-60-90 day plan

	Days 1–30: Foundation	Days 31–60: Pilot	Days 61–90: Scale
Build	Rules engine and dashboard v1 on real data; reconciliation sweep; audit log	Auto-approve for pilot group; WhatsApp templates approved and live; LLM remark parsing; discount approval flow	Intent-based payment link; org-wide rollout; SLA alerts
People	Ops training; owners and queues; teacher comms plan	Pilot teachers trained; weekly feedback	Cohort training for all teachers; champions
Measure	Baseline: orphan rate, payment-to-schedule, stuck count, duplicate rate	Auto-approval rate, SLA attainment, false-approval count (target 0)	Hours saved, turnaround vs SLA, revenue at risk trend
Decision	Go / no-go for pilot	Go / no-go for scale	Phase 2: instalment tracking, batch recommendation

5.5 Time and cost savings (illustrative: inputs are assumptions, replace with real numbers)

Item	Calculation	Result
Ops hours saved per week (sample zero-touch share)	300 renewals/week × 42% × 6 min ÷ 60	≈ 12.5 h/week
Ops hours saved if soft cases are one-tap too	300 × 67% × 6 min ÷ 60	≈ 20 h/week
Teacher time saved (form removed)	300 × 42% × 4 min ÷ 60	≈ 8.4 h/week
Value of Ops time (assumed ₹250/h loaded cost)	12.5 h × 52 weeks × ₹250	≈ ₹1.6 lakh/year
Revenue protected (sample)	Paid but unscheduled today	₹1,21,600 in this sample alone

The bigger prize is not hours; it is parents who paid and still get their class on time (retention). Tooling cost (n8n or Make plan, WhatsApp Business conversation fees, LLM calls only for exceptions) needs a quote; I expect it to be a small fraction of the hours saved, and I would confirm that before pilot.

5.6 Risks and mitigations

Risk	Mitigation
A wrong auto-approval schedules the wrong class for a paid child	Strict eligibility rules; shadow mode with 0-error gate; audit log; kill switch
Payment webhook arrives late or fails	15-minute sweep catches missed payments; Ops checks the gateway for Failed/pending UPI
Parents do not reply to the one-tap confirmation	Reminders at 24 h and 48 h, then an Ops phone call; SLA timer visible on the dashboard
Teachers keep using remarks/forms out of habit	Renewal Intent makes the right path the easy path; champion teachers; coaching view
WhatsApp template approval delays	Start approval in week 1; Slack/email fallback during pilot
Rules drift as policies change (discounts, instalments)	Ops lead owns the rule book; every change versioned and tested on the sample first

6. Assumptions, limits and what I would validate first

Assumption	Value used	How I would validate
Snapshot time	2026-11-03 18:00 IST (just after the newest record)	Use NOW() in production
Stuck threshold	12 hours after payment	From the assignment's dashboard brief; confirm with the Head of Ops
Sessions per term / scheduled at renewal	24; engine schedules all purchased sessions	Invoice 84901 shows only 2 of 24: confirm whether scheduling is rolling
Discount policy	Any discount needs approval	Ask for the real policy; turn pre-approved codes into an automatic rule
Manual minutes per renewal	6 min (illustrative)	Time two Ops execs on real renewals
Renewals per week	300 (the brief says "hundreds")	Pull the real number from the database
Zero-touch share	42% (67% with soft); from 12 outstanding sample renewals	Re-measure on 3 months of production data in shadow mode
Instalment coverage (84909)	Not assumed; held for Ops/Finance	Ask Finance how many sessions an instalment covers
Time zones (GCC / US tracks)	Times used as stored	Confirm how batch times are stored per region
Currency for GCC / US invoices	Shown as INR in the data	Confirm FX and gateway handling

What I did not do: I did not run the n8n workflow, WhatsApp, Slack or LLM calls against live services (credentials are placeholders); I did not record the Loom video (a talk track is in docs/); and the sample is too small to claim production percentages. Everything else described here is in the repository and was run on the provided CSVs.
